Simulated Annealing

To Solve 8-Queens problem

Algorithm 2 Simulated Annealing

current ← initial state
T ← a large positive value
while T > 0 **do**
    next ← a random neighbour of current
    ΔE ← current.cost - next.cost
    if $\Delta E > 0$ **then**
        current ← next
    else
        current ← next with probablity $p = e^{\frac{\Delta E}{T}}$
    end if
    decrease T
end while
return current
